## Periodic Strings

Define a $k$-periodic string as follows:
A string $\boldsymbol{s}$ is $\boldsymbol{k}$-periodic if the length of the string $|\boldsymbol{s}|$ is a multiple of $\boldsymbol{k}$, and if you chop the string up into $|\boldsymbol{s}| / \boldsymbol{k}$ substrings of length $\boldsymbol{k}$, then each of those substrings (except the first) is the same as the previous substring, but with its last character moved to the front.

For example, the following string is 3-periodic:

## abccabbcaabc

The above string can break up into substrings $a b c, c a b, b c a$, and $a b c$, and each substring (except the first) is a right-rotation of the previous substring ( $\mathrm{abc} \rightarrow \mathrm{cab} \rightarrow \mathrm{bca} \rightarrow \mathrm{abc}$ ).

Given a string, determine the smallest $\boldsymbol{k}$ for which the string is $k$-periodic.

## Input

Each input will consist of a single test case. Note that your program may be run multiple times on different inputs. The single line of input contains a string $s(\mathbf{1} \leq|s| \leq 100)$ consisting only of lowercase letters.

## Output

Output the integer $\boldsymbol{k}$, which is the smallest $\boldsymbol{k}$ for which the input string is $\boldsymbol{k}$-periodic.

| Sample Input | Sample Output |
| :--- | :--- |
| aaaaaaaa | 1 |
| abbaab.baab.ba | 2 |
| abcdef | 6 |
| abccabbcaabc | 3 |
